Testing of Hypothesis

($1^{st}/2^{nd}$ July, 2023)

Contact Session 7: Module 4: Hypothesis Testing

Contact Session	List of Topic Title	Reference
CS - 7	Sampling – random sampling and Stratified sampling, Sampling distribution – Central Limit theorem, Estimation– Interval Estimation, Confidence level	T1 & T2

Sampling: Terminology

POPULATION (Big data or Huge or Massive data)

A population is the set of all elements of interest in a particular study. The process of conducting a survey to collect data for the entire population is called a census.

SAMPLE (Small data)

A sample is a subset of the population. The process of conducting a survey to collect data for a sample is called a sample survey.

As one of its major contributions, statistics uses data from a sample to make estimates and test hypotheses about the characteristics of a population in the point of view of cost constraint. This part of statistics is called inferential statistics.

Terminology

Parameter

The various statistical characteristics or constants of a population such as Population mean, Population SD, Population Proportion etc., are called parameters.

Statistic

The various statistical functions of a sample such as sample mean, sample sd, sample proportion etc., are called statistics.

A statistic is a function of sample observations and is used to estimate its corresponding parameter. It is also known as estimator and its calculated value is called estimate.

A statistic is a variable and becomes a random variable if the sample is random sample.

Sampling

innovate achieve lead

- Sampling is a method or process of selecting samples from populations.
- Data are gathered from samples and conclusions are drawn about the population as a part of the inferential statistics process
- A sample provides a reasonable means for gathering useful decision-making information that might be otherwise unattainable and unaffordable.

Reasons for Sampling

Taking a sample instead of conducting a census offers several advantages

1. The sample can save money.

2. The sample can save time.

3. For given resources, the sample can broaden the scope of the study.

4. If accessing the population is impossible, the sample is the only option.

Types of Sampling

Sampling are of two types:

- Random Sampling
- Non-Random Sampling

Random Sampling	Non –Random Sampling
Simple Random Sampling	Judgemental Sampling
Stratified Sampling	Quota Sampling
Systematic Sampling	Convenience Sampling
Clustered Sampling	Snowball Sampling

Random Versus Non random Sampling

- In **random(probability)**sampling every unit of the population has the same probability of being selected into the sample.

- In **nonrandom(non-probability)**sampling not every unit of the population has the same probability of being selected into the sample.

Simple Random Sampling

In a simple random sample, every member of the population has an equal chance of being selected. The sampling frame should include the whole population.

To conduct this type of sampling, we can use tools like random number generators or other techniques that are based entirely on chance.

Example:
Suppose we want to select a simple random sample of 1000 employees of a social media marketing company. You assign a number to every employee in the company database from 1 to 1000, and use a random number generator to select 100 numbers.

Stratified Random Sampling

innovate achieve lead

- In this, the population is divided into non overlapping **subpopulations** called **strata**.
- The researcher then extracts a random sample from each of the subpopulations.
- The main reason for using stratified random sampling is that it has the potential for reducing sampling error.

- With stratified random sampling, the potential to match the sample closely to the population is greater than it is with simple random sampling because portions of the total sample are taken from different population subgroups.

Example:

- A survey about timekeeping might divide the population by time zone, then take 100 random samples per zone.

- A study on tax reform might stratify a population according to income, then take random samples from each stratum.

Non-probability sampling

Non-probability sampling is a sampling method that uses non-random criteria like the availability, geographical proximity, or expert knowledge of the individuals you want to research in order to answer a research question.

Non-probability sampling is used when the population parameters are either unknown or not possible to individually identify.

Example:

A visitors to a website that doesn't require users to create an account could form part of a non-probability sample.

Sampling Error

- **Sampling error** occurs *when the sample is not representative of the population*.

- When random sampling techniques are used to select elements for the sample, sampling error occurs by chance.

Population of Wages of employees of an organization

Sampling Variability

innovate achieve lead

- The term "sampling variability" refers to the fact that the statistical information from a sample (called a *statistic*) will vary as the random sampling is repeated.

- **Sampling variability** will **decrease** as the **sample size increases.**

- the samples must be randomly chosen, must be of the same size (not smaller than 30), and the more samples that are used, the more reliable the information gathered will be.

Do you consider these sample means and sample SDs as variable?

If yes, should we not describe the distribution of these variables?

The distributi on of the sample estimates is called sampling distributi on

For example the distribution of sample means is called Sampling distribution of mean

Definition

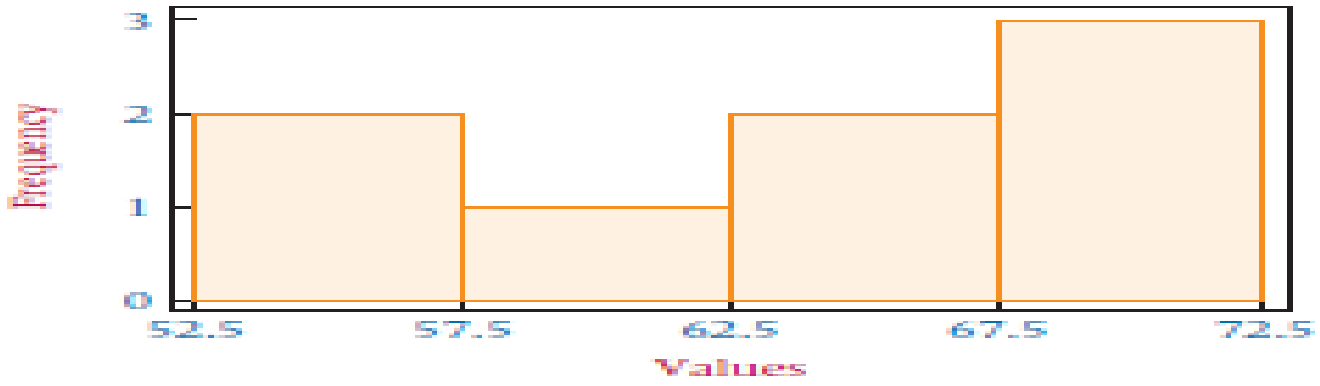
- The probability distribution of a statistic (sample estimate) is called sampling distribution.
- The sampling distribution of a statistic depends on the distribution of the population, the size of the sample, and the method of sample selection.

Sampling Distribution Of $\bar{x}$

- The sample mean is one of the more common statistics used in the inferential process.
- The **distribution** of the values of the sample mean ($\bar{x}$) in repeated **samples** is called the **sampling distribution of $\bar{x}$**
- One way to examine the distribution possibilities is to take a population with a particular distribution, randomly select samples of a given size, compute the sample means, and attempt to determine how the means are distributed.

Example

- Suppose a small finite population consists of only $N = 8$ numbers:
- 54 55 59 63 64 68 69 70
- Using an Excel-produced histogram, we can see the shape of the distribution of this population of data.



- Suppose we take all possible samples of size $n = 2$ from this population with replacement.

Example

The result is the following pairs of data.

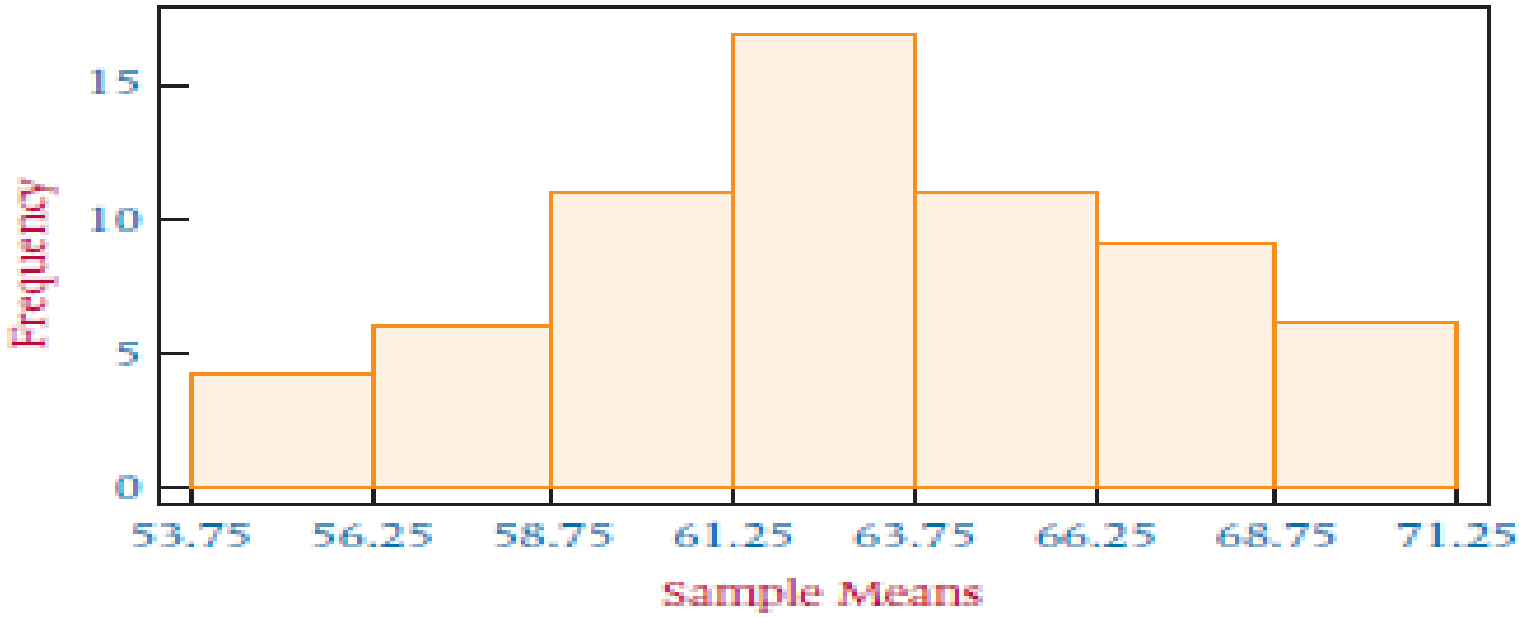
(54,54)	(55,54)	(59,54)	(63,54)
(54,55)	(55,55)	(59,55)	(63,55)
(54,59)	(55,59)	(59,59)	(63,59)
(54,63)	(55,63)	(59,63)	(63,63)
(54,64)	(55,64)	(59,64)	(63,64)
(54,68)	(55,68)	(59,68)	(63,68)
(54,69)	(55,69)	(59,69)	(63,69)
(54,70)	(55,70)	(59,70)	(63,70)
(64,54)	(68,54)	(69,54)	(70,54)
(64,55)	(68,55)	(69,55)	(70,55)
(64,59)	(68,59)	(69,59)	(70,59)
(64,63)	(68,63)	(69,63)	(70,63)
(64,64)	(68,64)	(69,64)	(70,64)
(64,68)	(68,68)	(69,68)	(70,68)
(64,69)	(68,69)	(69,69)	(70,69)
(64,70)	(68,70)	(69,70)	(70,70)

The means of each of these samples follow.

54	54.5	56.5	58.5	59	61	61.5	62
54.5	55	57	59	59.5	61.5	62	62.5
56.5	57	59	61	61.5	63.5	64	64.5
58.5	59	61	63	63.5	65.5	66	66.5
59	59.5	61.5	63.5	64	66	66.5	67
60	61.5	63.5	65.5	66	68	68.5	69
61.5	62	64	66	66.5	68.5	69	69.5
62	62.5	64.5	66.5	67	69	69.5	70

Example

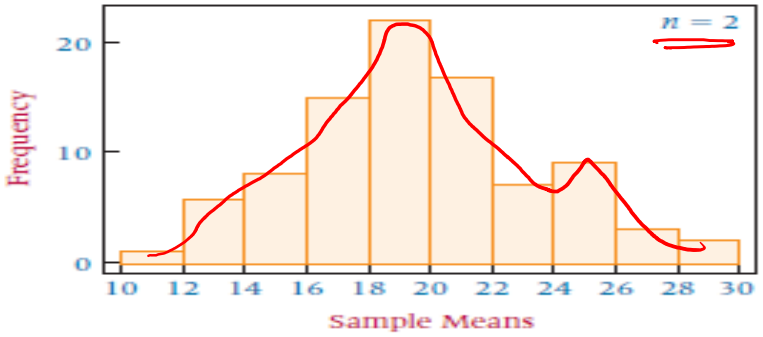
- Again using an Excel-produced histogram, we can see the shape of the distribution of these sample means.

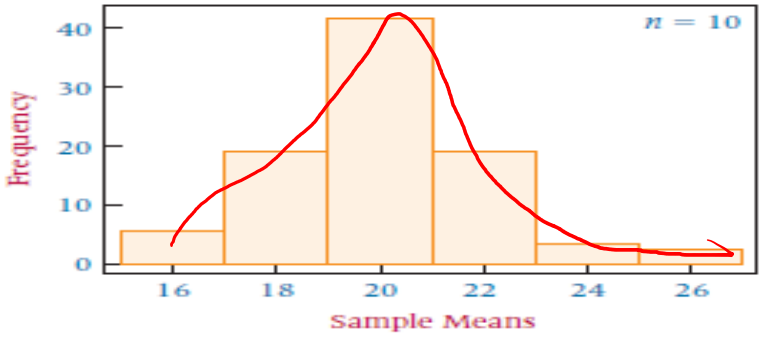


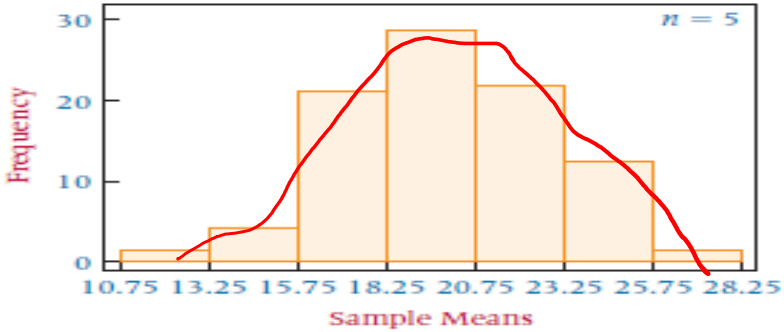
Conclusions

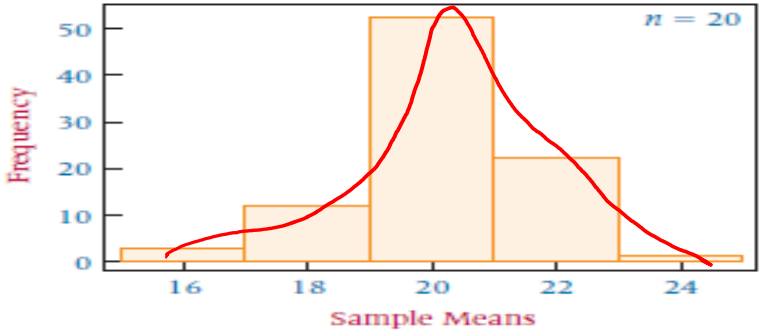
- Notice that the shape of the histogram for sample means is quite unlike the shape of the histogram for the population.
- The sample means appear to “pile up” toward the middle of the distribution and “tail off” toward the extremes.
- As sample sizes become much larger, the sample mean distributions begin to approach a **normal distribution** and the variation among the means decreases.

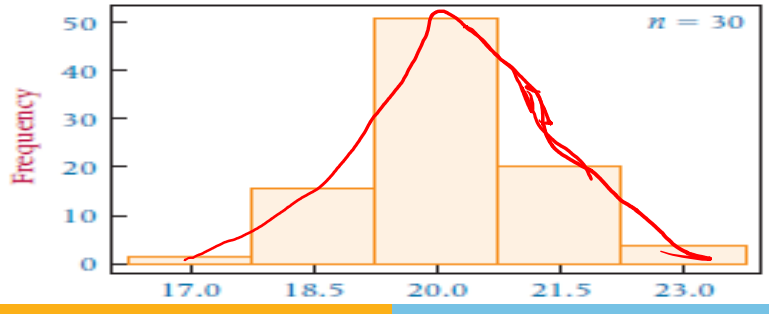
Sample Means from 90 Samples Ranging in Size from n = 2 to n = 30 from a Uniformly Distributed Population with a = 10 and b = 30



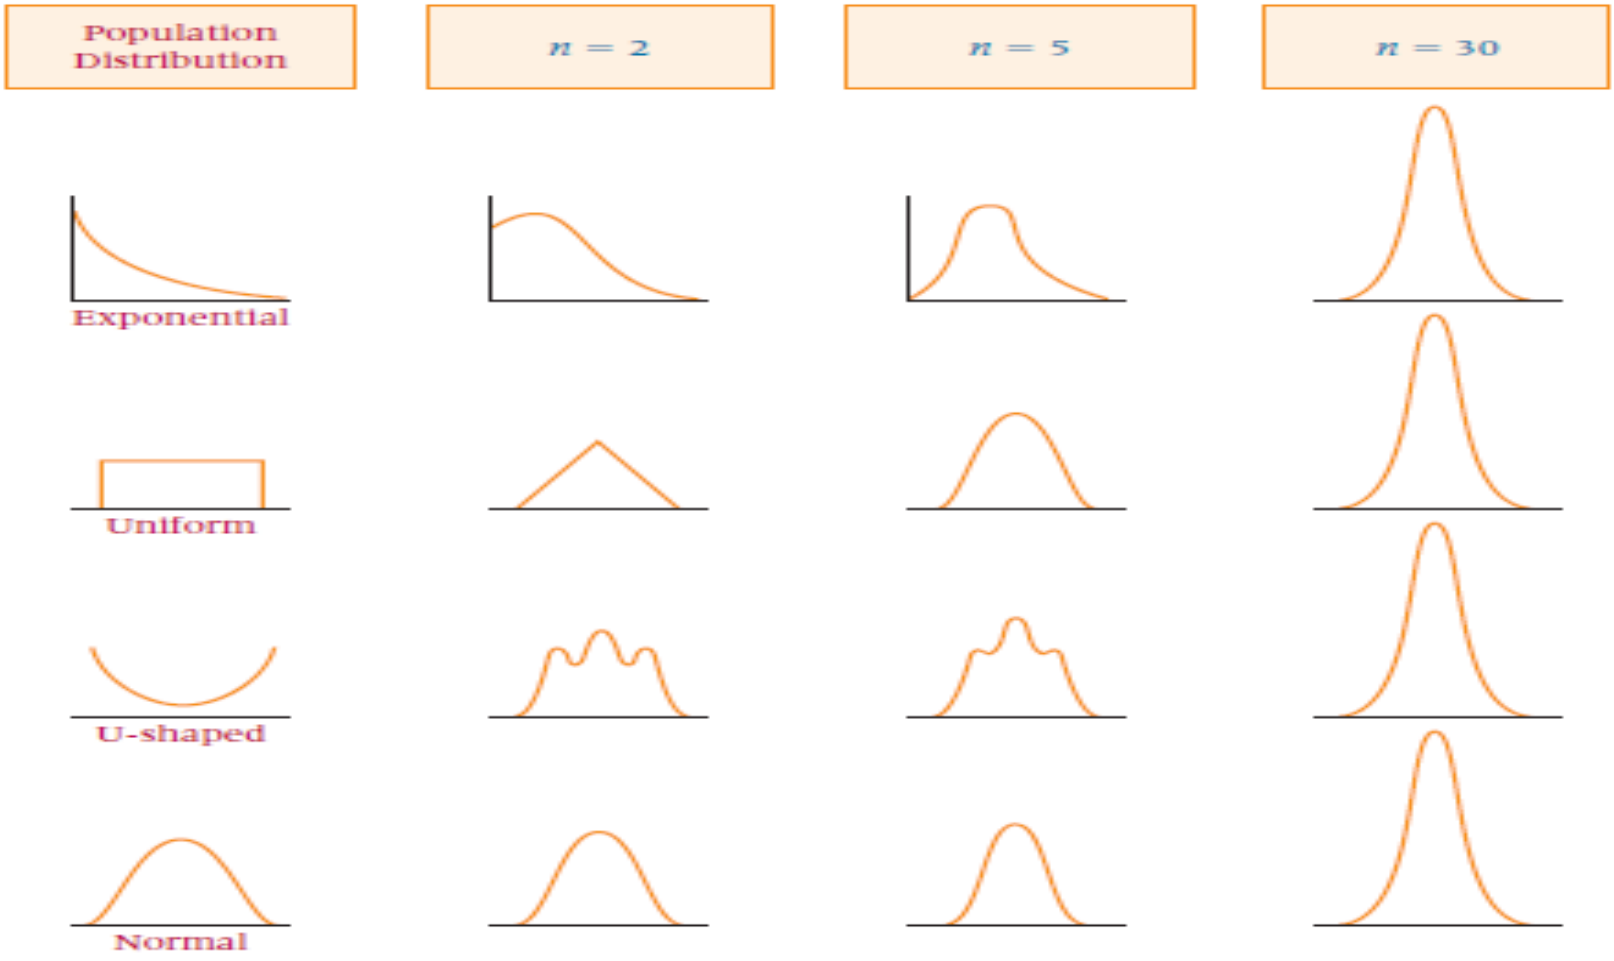








Shapes of the Distributions of Sample Means



Central Limit Theorem

- If samples of size *n* are drawn randomly from a population that has a mean of μ and a standard deviation of σ, the sample means, $\bar{x}$, are approximately normally distributed for sufficiently large sample sizes (*n* >= 30) regardless of the shape of the population distribution.

- If the population is normally distributed, the sample means are normally distributed for any size sample.

- From mathematical expectation

$$\mu_{\bar{x}} = \mu \qquad \sigma_{\bar{x}} = \frac{\sigma}{\sqrt{n}}$$

Z score for sample means

- The central limit theorem states that sample means are normally distributed regardless of the shape of the population for large samples and for any sample size with normally distributed populations.
- Thus, **sample means** can be **analyzed** by using ***z* scores**
- The formula to determine z scores for individual values from a normal distribution:

$$z = \frac{x - \mu}{\sigma}$$

- If sample means are normally distributed, the z score formula applied to sample means would be

$$z = \frac{\bar{x} - \mu_{\bar{x}}}{\sigma_{\bar{x}}}$$

- The standard deviation of the statistic of interest is $\sigma_{\bar{x}}$, sometimes referred to as the **standard error of the mean.**

Example

Suppose the mean expenditure per customer at a tire store is $85.00, with a standard deviation of $9.00.

If a random sample of 40 customers is taken, what is the probability that the sample average expenditure per customer for this sample will be $87.00 or more?

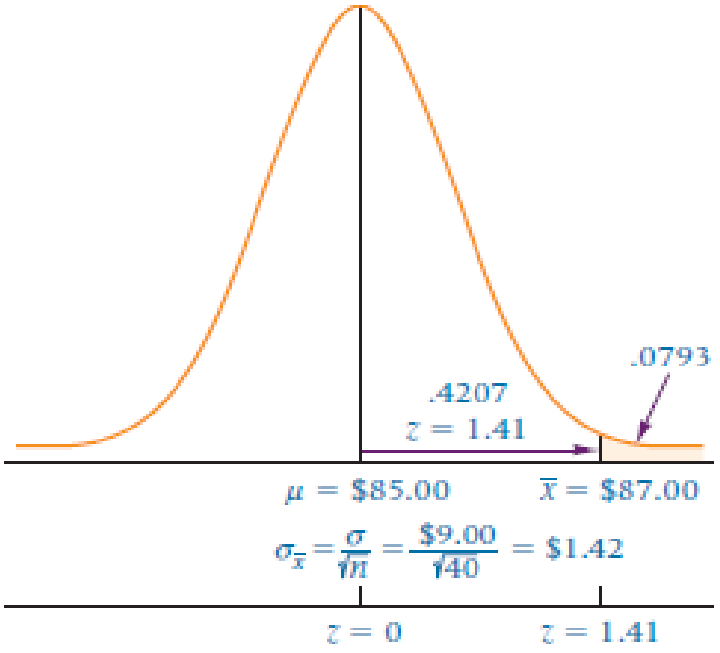
Solution

Because the sample size is greater than 30, the central limit theorem

Can be used, and the sample means are normally distributed.

μ= $85 σ= $9

$$z = \frac{\bar{x} - \mu}{\frac{\sigma}{\sqrt{n}}} = \frac{\$87.00 - \$85.00}{\frac{\$9.00}{\sqrt{40}}} = \frac{\$2.00}{\$1.42} = 1.41$$



STANDARD NORMAL DISTRIBUTION: Table Values Represent AREA to the LEFT of the Z score.

Example

Suppose that during any hour in a large department store, the average number of shoppers is 448, with a standard deviation of 21 shoppers.

What is the probability that a random sample of 49 different shopping hours will yield a sample mean between 441 and 446 shoppers?

Solution

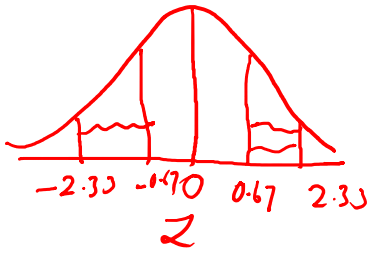
For this problem, μ= 448, σ= 21, and n = 49. The problem is to determine

P(441<= $\bar{x}$ <=446).

The following

$$z = \frac{441 - 448}{\frac{21}{\sqrt{49}}} = \frac{-7}{3} = -2.33$$

$$z = \frac{446 - 448}{\frac{21}{\sqrt{49}}} = \frac{-2}{3} = -0.67$$



$$P(-2.33 < Z < -0.67)$$

$$= P(0.67 < Z < 2.33)$$

$$= F(2.33) - F(0.67)$$

$$= 0.9901 - 0.7485$$

Sampling from a Finite Population

- The earlier example was based on the assumption that the population was infinitely or extremely large.

- In cases of a finite population, *a statistical adjustment can be made to the z formula for sample means*. The adjustment is called the **finite correction factor**

$$\sqrt{\frac{N-n}{N-1}}.$$

- Following is the z formula for sample means when samples are drawn from finite populations.

$$z = \frac{\bar{x} - \mu}{\frac{\sigma}{\sqrt{n}}\sqrt{\frac{N-n}{N-1}}}$$

Rules for finite population

- As the size of the finite population becomes larger in relation to sample size, the finite correction factor approaches 1.

- In theory, whenever researchers are working with a finite population, they can use the finite correction factor.

- A rough rule of thumb for many researchers is that, if the sample size is **less** than **5%** of the finite population size or ***n/N* < 0.05**, the finite correction factor does **not** significantly modify the solution.

Example

A production company's 350 hourly employees average 37.6 years of age, with a standard deviation of 8.3 years.

If a random sample of 45 hourly employees is taken, what is the probability that the sample will have an average age of less than 40 years?

Solution

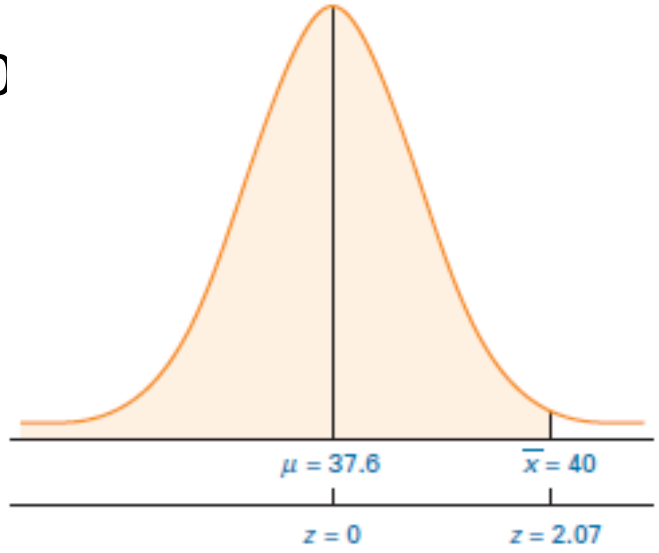
- The population mean is 37.6, with a population standard deviation of 8.3.
- The sample size is 45, but it is being drawn from a finite population of 350; that is, n = 45 and N = 350.
- The sample mean under consideration is 40
- Using the z formula with the finite correction factor gives

$$z = \frac{40 - 37.6}{\frac{8.3}{\sqrt{45}}\sqrt{\frac{350 - 45}{350 - 1}}} = \frac{2.4}{1.157} = 2.07$$

...solution

- This z value yields a probability of .480
- Therefore, the probability of getting a
- sample average age of less than
- 40 years is **.4808 + .5000 = .9808.**

0.98077
≃ 0.9808



Sampling Distribution Of Sample Proportion

- If research results in ***countable*** items such as how many people in a sample have a flexible work schedule, the sample proportion is often the statistic of choice.

SAMPLE PROPORTION

$$\hat{p} = \frac{x}{n}$$

where

x = number of items in a sample that have the characteristic
n = number of items in the sample

Example

- In a sample of 100 factory workers, 30 workers might belong to a union.

- The value of sample proportion for this characteristic, union membership, is

  30/100 = 0 .30 = 30%

How does a researcher use the sample proportion in analysis?

innovate achieve lead

- The central limit theorem applies to sample proportions in that the normal distribution approximates the shape of the distribution of sample proportions

- If $n*p > 15$ and $n*q > 15$(p is the population proportion and $q = 1 - p$).

- The mean of sample proportions for all samples of size n randomly drawn from a population is p (the population proportion) and the standard deviation of sample proportions is $\sqrt{\frac{\hat{p} \cdot \hat{q}}{n}}$

- sometimes referred to as the **standard error of the proportion**

Z Formula For Sample Proportions

For $n*p > 1$ 5 and $n*q > 15$

$$z = \frac{\hat{p} - p}{\sqrt{\frac{p \cdot q}{n}}}$$

where

$\hat{p}$ = sample proportion
n = sample size
p = population proportion
$q = 1 - p$

Example

Suppose 60% of the electrical contractors in a region use a particular brand of wire. What is the probability of taking a random sample of size 120 from these electrical contractors and finding that .50 or less use that brand of wire?

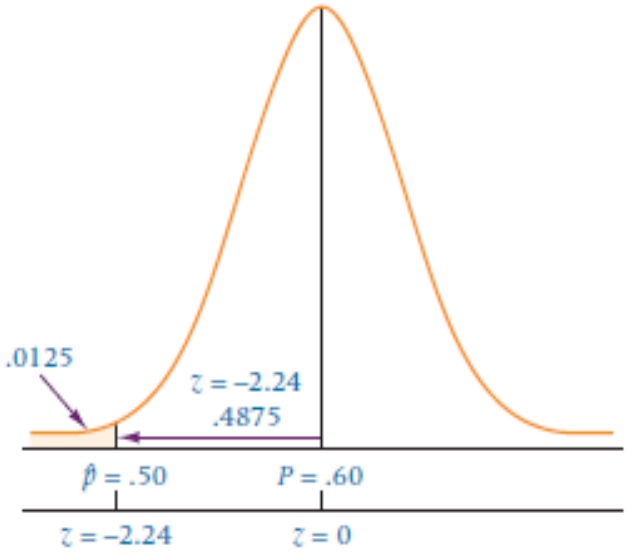
Solution

$p = .60 \quad \hat{p} = .50 \quad n = 120$

The z formula yields

$$z = \frac{.50 - .60}{\sqrt{\frac{(.60)(.40)}{120}}} = \frac{-.10}{.0447} = -2.24$$

= -2.24 is .4875.



For z < -2.24 (the tail of the distribution), the answer is .5000 - .4875 = **.0125**.

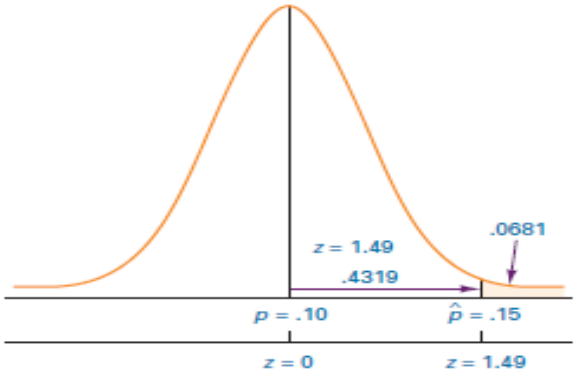
Example

If 10% of a population of parts is defective, what is the probability of randomly selecting 80 parts and finding that 12 or more parts are defective?

Solution

Here, $p = .10$, $\hat{p} = 12/80 = .15$, and $n = 80$. Entering these values in the z formula yields

$$z = \frac{.15 - .10}{\sqrt{\frac{(.10)(.90)}{80}}} = \frac{.05}{.0335} = 1.49$$



- The probability of .4319 for a z value of 1.49, which is the area between the sample proportion, .15, and the population proportion, .10. The answer to the question is

$$P(\hat{p} \geq .15) = .5000 - .4319 = .0681.$$

Forms Of Statistical Inference

innovate achieve lead

- Three forms of statistical inference

- Point estimation
- Interval estimation
- Hypothesis testing

Point Estimate

- A **point estimate** is a statistic taken from a sample that is used to estimate a population parameter.
- A point estimate is only as good as the representativeness of its sample.
- If other random samples are taken from the population, the point estimates derived from those samples are likely to vary.

Interval Estimate

- Because of variation in sample statistics, estimating a population parameter with an interval estimate is often preferable to using a point estimate.

- An interval estimate (**confidence interval**) is a range of values within which the analyst can declare, with some confidence, the population parameter lies.

Confidence Interval to Estimate μ

innovate achieve lead

100(1 − α)% CONFIDENCE INTERVAL TO ESTIMATE μ: σ KNOWN (8.1)

$$\bar{x} \pm z_{\alpha/2}\frac{\sigma}{\sqrt{n}}$$

or

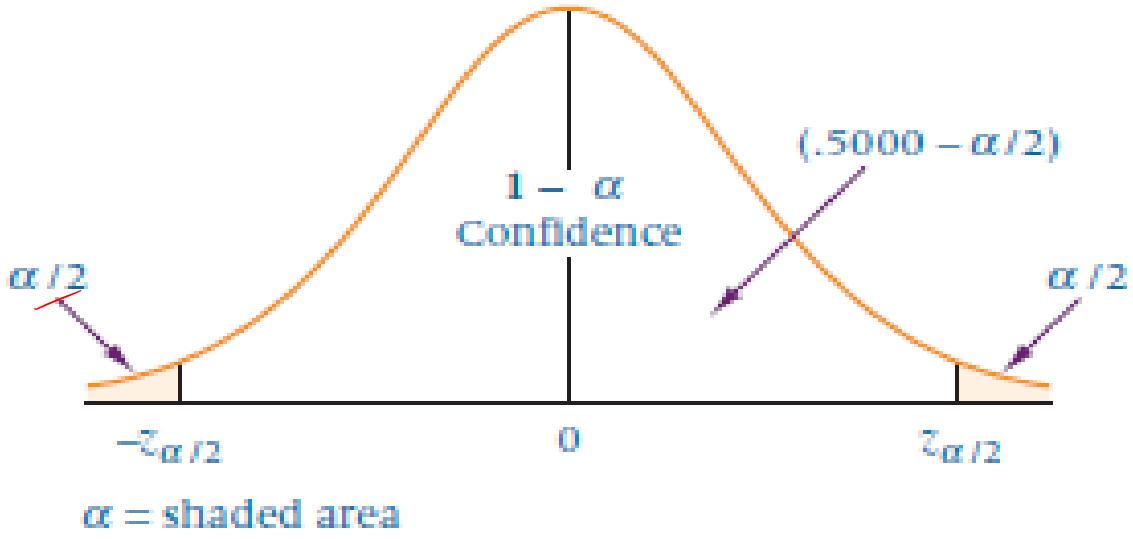
$$\bar{x} - z_{\alpha/2}\frac{\sigma}{\sqrt{n}} \leq \mu \leq \bar{x} + z_{\alpha/2}\frac{\sigma}{\sqrt{n}}$$

where

α = the area under the normal curve outside the confidence interval area

$\alpha/2$ = the area in one end (tail) of the distribution outside the confidence interval

Confidence Intervals



Standard normal variable value $z_{\alpha/2}$ (Table Value)	Level of significance ∝		
	1%=0.01	5%=0.05	10%=0.1
∝/2	0.01/2 =0.005	0.05/2=0.025	0.1/2=0.05
$F(z_{\alpha/2})$=1-∝/2 $P(Z<=z_{\alpha/2})$= 1-∝/2	P(Z<=2.58)= 0.995 then $z_{\alpha/2}$= 2.58	P(Z<=1.96)= 0.975 then $z_{\alpha/2}$= 1.96	P(Z<=1.645)= 0.95 then $z_{\alpha/2}$= 1.645

Example

In the cellular telephone company, problem of estimating the population mean number of minutes called per residential user per month, from the sample of 85 bills it was determined that the sample mean is 510 minutes.

Suppose past history and similar studies indicate that the population standard deviation is 46 minutes.

Determine a 95% confidence interval.

Solution

The business researcher can now complete the cellular telephone problem. To determine a 95% confidence interval for $\bar{x} = 510$, $\sigma = 46$, $n = 85$, and $z = 1.96$, the researcher estimates the average call length by including the value of z in formula 8.1.

$$510 - 1.96\frac{46}{\sqrt{85}} \leq \mu \leq 510 + 1.96\frac{46}{\sqrt{85}}$$

$$510 - 9.78 \leq \mu \leq 510 + 9.78$$

$$500.22 \leq \mu \leq 519.78$$

…solution

- The confidence interval is constructed from the point estimate, which in this problem is 510 minutes, and the error of this estimate, which is 9.78 minutes.

- The resulting confidence interval is 500.22 <= μ <= 519.78.

- The cellular telephone company researcher is 95%, confident that the average length of a call for the population is between 500.22 and 519.78 minutes.

Example

A study is conducted in a company that employs 800 engineers. A random sample of 50 engineers reveals that the average sample age is 34.3 years. Historically, the population standard deviation of the age of the company's engineers is approximately 8 years.

Construct a 98% confidence interval to estimate the average age of all the engineers in this company.

Solution

- This problem has a finite population. The sample size, 50, is greater than 5% of the population, so the finite correction factor may be helpful.
- In this case N = 800, n = 50, $\bar{x}$= 34.3 and σ= 8
- The z value for a 98% confidence interval is 2.33

$$\bar{x} - z_{\alpha/2}\frac{\sigma}{\sqrt{n}}\sqrt{\frac{N-n}{N-1}} \qquad \bar{x} + z_{\alpha/2}\frac{\sigma}{\sqrt{n}}\sqrt{\frac{N-n}{N-1}}$$

$$34.30 - 2.33\frac{8}{\sqrt{50}}\sqrt{\frac{750}{799}} \le \mu \le 34.30 + 2.33\frac{8}{\sqrt{50}}\sqrt{\frac{750}{799}}$$

$$34.30 - 2.55 \le \mu \le 34.30 + 2.55$$

$$31.75 \le \mu \le 36.85$$

Estimating The Population Proportion

- Methods similar to those used earlier can be used to estimate the population proportion.
- The central limit theorem for sample proportions led to the following formula

$$z = \frac{\hat{p} - p}{\sqrt{\frac{p \cdot q}{n}}}$$

- where q = 1 - p. Recall that this formula can be applied only when n*p and n*q are **greater** than **5**.

- for confidence interval purposes only and for large sample sizes— is substituted for p in the denominator, yielding

$$z = \frac{\hat{p} - p}{\sqrt{\frac{\hat{p} \cdot \hat{q}}{n}}}$$

Confidence Interval To Estimate P

$$\hat{p} - z_{\alpha/2}\sqrt{\frac{\hat{p}\cdot\hat{q}}{n}} \leq p \leq \hat{p} + z_{\alpha/2}\sqrt{\frac{\hat{p}\cdot\hat{q}}{n}}$$

where

$\hat{p}$ = sample proportion
$\hat{q} = 1 - \hat{p}$
p = population proportion
n = sample size

In this formula, $\hat{p}$ is the point estimate and $\pm z_{\alpha/2}\sqrt{\frac{\hat{p}\cdot\hat{q}}{n}}$ is the error of the estimation.

Example

A study of 87 randomly selected companies with a telemarketing operation revealed that 39% of the sampled companies used telemarketing to assist them in order processing.

Using this information, how could a researcher estimate the *population* proportion of telemarketing companies that use their telemarketing operation to assist them in order processing?

Solution

The sample proportion, $\hat{p} = .39$, is the *point estimate* of the population proportion, p. For $n = 87$ and $\hat{p} = .39$, a 95% confidence interval can be computed to determine the interval estimation of p. The z value for 95% confidence is 1.96. The value of $\hat{q} = 1 - \hat{p} = 1 - .39 = .61$. The confidence interval estimate is

$$.39 - 1.96\sqrt{\frac{(.39)(.61)}{87}} \leq p \leq .39 + 1.96\sqrt{\frac{(.39)(.61)}{87}}$$

$$.39 - .10 \leq p \leq .39 + .10$$

$$.29 \leq p \leq .49$$

Example

Coopers & Lybrand surveyed 210 chief executives of fast-growing small companies. Only 51% of these executives had a management succession plan in place. A spokesperson for Cooper & Lybrand said that many companies do not worry about management succession unless it is an immediate problem. However, the unexpected exit of a corporate leader can disrupt and unfocus a company for long enough to cause it to lose its momentum.

Use the data given to compute a 92% confidence interval to estimate the proportions

Solution

The point estimate is the sample proportion given to be .51. It is estimated that .51, or 51% of all fast-growing small companies have a management succession plan. Realizing that the point estimate might change with another sample selection, we calculate a confidence interval.

The value of n is 210; $\hat{p}$ is .51, and $\hat{q} = 1 - \hat{p} = .49$. Because the level of confidence is 92%, the value of $z_{.04} = 1.75$. The confidence interval is computed as

$$\hat{p} - z_{\alpha/2}\sqrt{\frac{\hat{p}(1-\hat{p})}{n}} \le p \le \hat{p} + z_{\alpha/2}\sqrt{\frac{\hat{p}(1-\hat{p})}{n}}$$

$$.51 - 1.75\sqrt{\frac{(.51)(.49)}{210}} \le p \le .51 + 1.75\sqrt{\frac{(.51)(.49)}{210}}$$

$$.51 - .06 \le p \le .51 + .06$$

$$.45 \le p \le .57$$

Question :

Car mufflers are constructed by nearly automatic machine. One manufacturer finds that, for any type of car muffler, the time for a person to set up and complete a production run has a normal distribution with mean 1.82 hours and standard deviation 1.20.

What is the probability that the sample mean of the next 40 runs will be from 1.65 to 2.04 hours ?

Question :

Engine bearings depend on a film of oil to keep shaft and bearing surfaces separated. Insufficient lubrication causes bearings to be overloaded. The insufficient lubrication can be modeled as a random variable having a mean 0.6520 ml and standard deviation 0.0125 ml.

The sample mean of insufficient lubrication will be obtained frm a random sample of 60 bearings.

What is the probability that sample mean $\bar{x}$ will be between 0.600 ml and 0.640 ml ?

Question :

A random sample size of n = 100 is taken from a population with $\sigma = 5.1$.

Given that the sample mean is $\bar{x} = 2.16$,

construct a 95% confidence interval for the population mean μ.

Question :

With reference to the data in section 2.1 (of R1) , we have

n = 50 , $\overline{x}$ = 305.58 nm, and s2 = 1366.86(hence, s=36.97 nm),

Construct a 99% confidence interval for the population mean of all nanopillars.

Exercise

A survey was taken of U.S. companies that do business with firms in India. One of the questions on the survey was: Approximately how many years has your company been trading with firms in India?

A random sample of 44 responses to this question yielded a mean of 10.455 years. Suppose the population standard deviation for this question is 7.7 years.

Using this information, construct a 90% confidence interval for the mean number of years that a company has been trading in India for the population of U.S. companies trading with firms in India.

Solution

Here, n= 44, $\bar{x}$= 10.455 and σ= 7.7. To determine the value of $z_{\alpha/2}$, divide the 90% confidence in half, or take .5000 - α/2= .5000 - .0500= 0.45 where α= 10%.

Z table yields a z value of 1.645 for the area of .45

The confidence interval is

$$\bar{x} - z\frac{\sigma}{\sqrt{n}} \leq \mu \leq \bar{x} + z\frac{\sigma}{\sqrt{n}}$$

$$10.455 - 1.645\frac{7.7}{\sqrt{44}} \leq \mu \leq 10.455 + 1.645\frac{7.7}{\sqrt{44}}$$

$$10.455 - 1.910 \leq \mu \leq 10.455 + 1.910$$

$$8.545 \leq \mu \leq 12.365$$

Exercise

A clothing company produces men's jeans. The jeans are made and sold with either a regular cut or a boot cut. In an effort to estimate the proportion of their men's jeans market in Oklahoma City that prefers boot-cut jeans, the analyst takes a random sample of 212 jeans sales from the company's two Oklahoma City retail outlets. Only 34 of the sales were for boot-cut jeans.

Construct a 90% confidence interval to estimate the proportion of the population in Oklahoma City who prefer boot-cut jeans.

Solution

The sample size is 212, and the number preferring boot-cut jeans is 34. The sample proportion is $\hat{p} = 34/212 = .16$. A point estimate for boot-cut jeans in the population is .16, or 16%. The z value for a 90% level of confidence is 1.645, and the value of $\hat{q} = 1 - \hat{p} = 1 - .16 = .84$. The confidence interval estimate is

$$.16 - 1.645\sqrt{\frac{(.16)(.84)}{212}} \le p \le .16 + 1.645\sqrt{\frac{(.16)(.84)}{212}}$$

$$.16 - .04 \le p \le .16 + .04$$

$$.12 \le p \le .20$$
